Version 1 Features

1. Simple Sign-Up and Student Profile

Students need an account so their assignments, notes, and study plans are saved. V1 only needs the basics: email or school login, grade level, and subjects. Grade level also lets the AI adjust its language for a middle schooler versus a college student.

2. Assignment and Test Tracker

This is the foundation of the app, because the study plans and reminders all depend on knowing what is due and when. It's technically simple (basic data entry), and it gives students a reason to open the app every day.

3. Reminders and Notifications

A tracker only helps if students see it in time. Push reminders for deadlines, tests, and study sessions directly address the stress of missed due dates described in your problem statement, and they're easy to build alongside the tracker.

4. Personalized Study Plans

This feature turns the tracker's data into an actionable schedule and sets the app apart from a plain to-do list. V1 can keep it straightforward: a schedule built from test dates and the subjects entered, with no complex personalization yet.

5. Notes Input (Paste or Type)

The quizzes and flashcards need something to work from. A basic text box where

students paste or type their notes unlocks both features without the complexity of photo scanning or file uploads, which can come later.

6. AI-Generated Quizzes and Smart Flashcards

I've grouped these because they use the same input (student notes) and the same AI pipeline, so building both costs little more than building one. Practice testing is one of the most effective study methods, and these features deliver the app's most visible value at launch.

7. AI Topic Explainer

This is one of the simplest AI features to build, since it only needs a question and a clear answer, and it helps students who are stuck instead of sending them to other websites. Together with the features above, it completes the "organize, learn, practice" loop.

Future Features

1. Progress Reports

These need real usage data, such as quiz scores and completed study sessions, before they can say anything meaningful. They belong in an update once V1 has been collecting that data.

2. Adaptive Learning System

This builds on progress data and requires more advanced logic to adjust quizzes and plans automatically. V1 should first prove that the basic versions work and that students use them.

3. School Calendar and Learning Platform Integrations

Connecting to Google Classroom, Canvas, or similar systems involves outside APIs, school permissions, and privacy rules, especially for younger students. It would be convenient, but students can enter dates manually at first.

4. Voice-Based AI Tutoring

Voice adds speech recognition, audio generation, and extra testing for accuracy and accessibility. It’s a nice enhancement, but the text-based Topic Explainer covers the same need for now.

5. Group Study Rooms

Collaboration needs real-time syncing, sharing controls, and moderation, especially with

minors on the platform. This is the most complex and highest-risk idea, so it should wait until the app has an established user base.

6. Photo and Document Scanning for Notes

Letting students snap a picture of handwritten notes or upload a PDF would be very convenient, but it requires text recognition (OCR) that has to handle messy handwriting. Typed or pasted notes work fine for launch.

7. Gamification (Streaks, Badges, Rewards)

Study streaks and achievements could boost motivation and daily use, but they work best once you know how students actually use the app. Adding them too early risks building rewards for the wrong behaviors.

8. Parent and Teacher Views

Giving parents or teachers a read-only view of progress could help younger students stay on track. It also raises privacy, consent, and account-linking questions that need careful design, so it’s better added after V1 has proven itself.
